#### Data Assimilation Research Testbed Tutorial

Section 12: Adaptive Inflation

Version 1.0: June, 2005

1. For observed variable, have estimate of prior-observed inconsistency

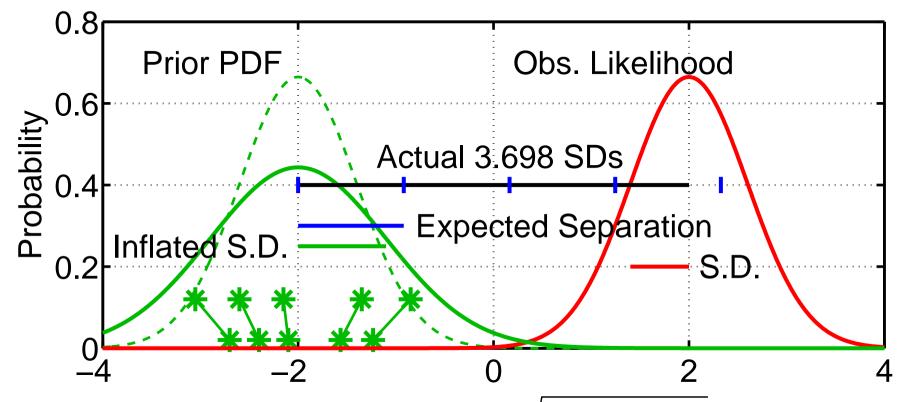

2. Expected(prior mean - observation) =  $\sqrt{\sigma_{prior}^2 + \sigma_{obs}^2}$ .

Assumes that prior and observation are supposed to be unbiased. Is it model error or random chance?

9/7/06

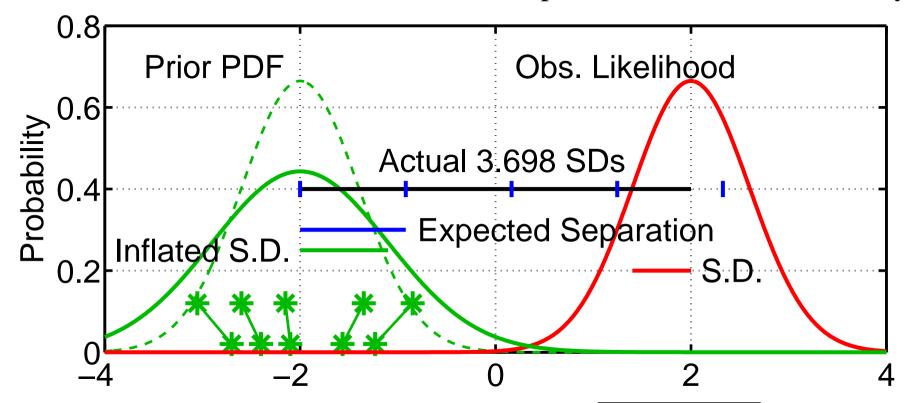

1. For observed variable, have estimate of prior-observed inconsistency

- 2. Expected(prior mean observation) =  $\sqrt{\sigma_{prior}^2 + \sigma_{obs}^2}$ .
- 3. Inflating increases expected separation.

  Increases 'apparent' consistency between prior and observation.

1. For observed variable, have estimate of prior-observed inconsistency

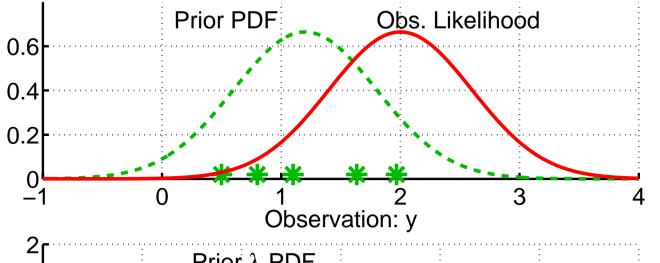

Distance, D, from prior mean y to obs. is  $N(0, \sqrt{\lambda \sigma_{prior}^2 + \sigma_{obs}^2}) = N(0, \theta)$ 

Prob. y<sub>o</sub> is observed given  $\lambda$ :  $p(y_o|\lambda) = (2\Pi\theta^2)^{-1/2} \exp(-D^2/2\theta^2)$ 

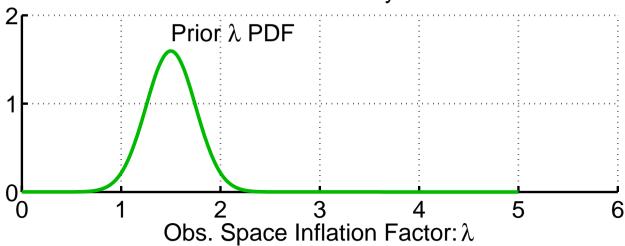

Assume prior is gaussian;  $p(\lambda, t_k | Y_{t_{k-1}}) = N(\overline{\lambda}_p, \sigma_{\lambda, p}^2)$ .

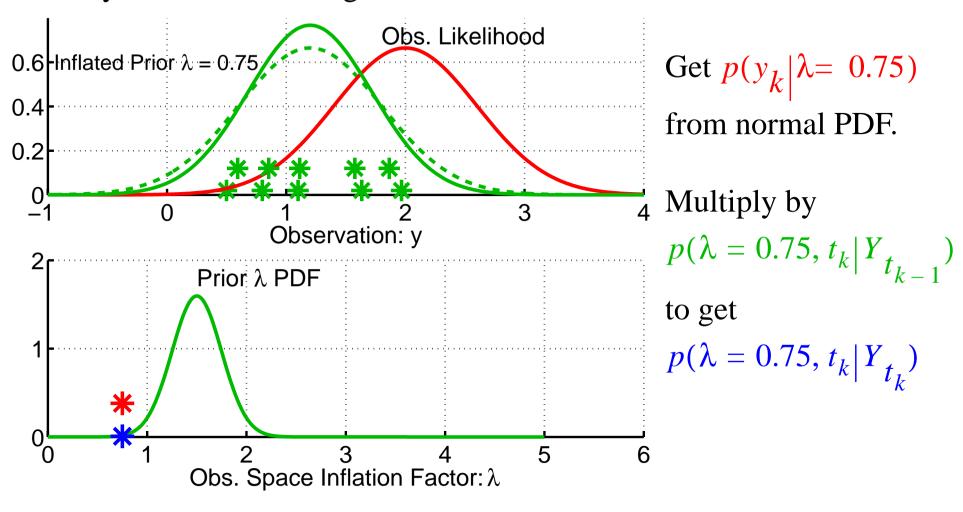

We've assumed a gaussian for prior  $p(\lambda, t, | V)$ 

 $p(\lambda, t_k | Y_{t_{k-1}}).$ 

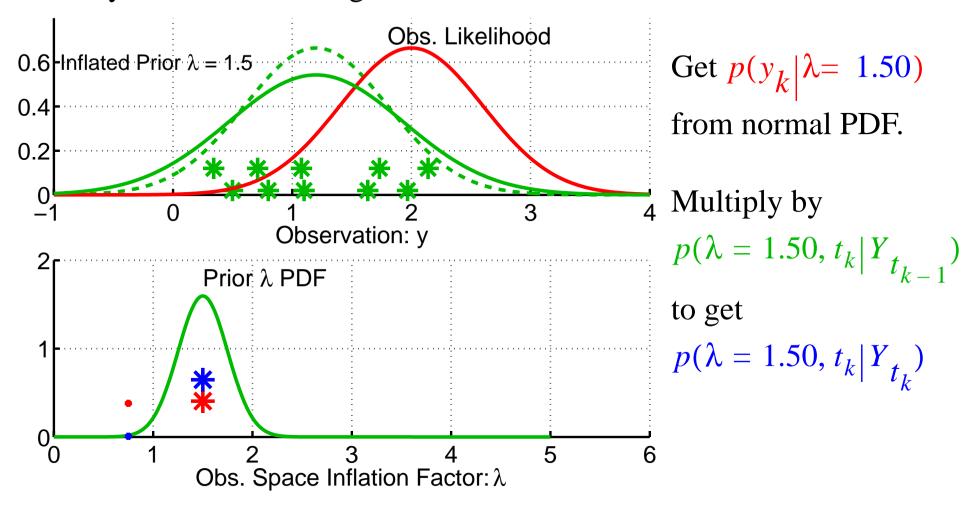

Recall that  $p(y_k|\lambda)$  can be evaluated from normal PDF.

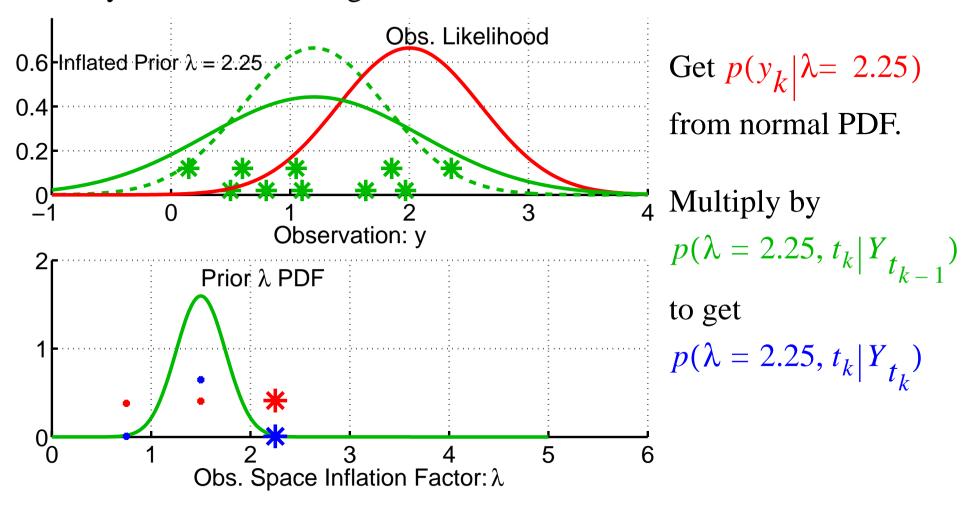

$$p(\lambda, t_k | Y_{t_k}) = p(y_k | \lambda) p(\lambda, t_k | Y_{t_{k-1}}) / normalization.$$

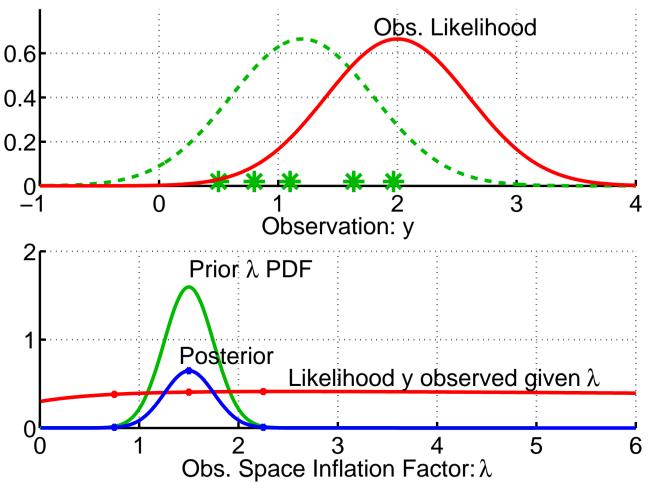

$$p(\lambda, t_k | Y_{t_k}) = p(y_k | \lambda) p(\lambda, t_k | Y_{t_{k-1}}) / normalization.$$

$$p(\lambda, t_k | Y_{t_k}) = p(y_k | \lambda) p(\lambda, t_k | Y_{t_{k-1}}) / normalization.$$

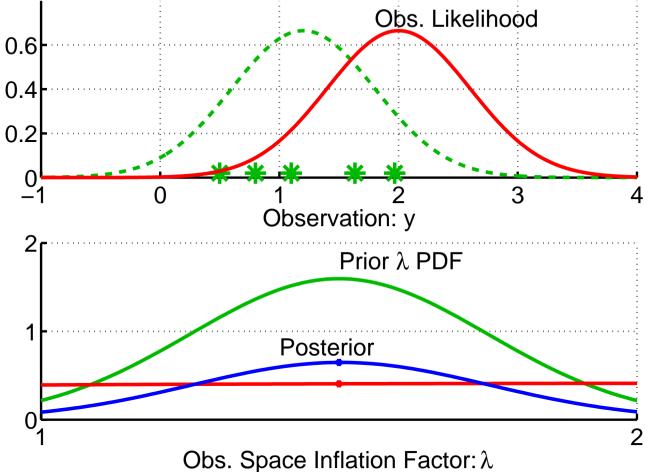

$$p(\lambda, t_k | Y_{t_k}) = p(y_k | \lambda) p(\lambda, t_k | Y_{t_{k-1}}) / normalization.$$

Repeat for a range of values of  $\lambda$ .

Now must get posterior in same form as prior (gaussian).

 $p(\lambda, t_k | Y_{t_k}) = p(y_k | \lambda) p(\lambda, t_k | Y_{t_{k-1}}) / normalization.$ 

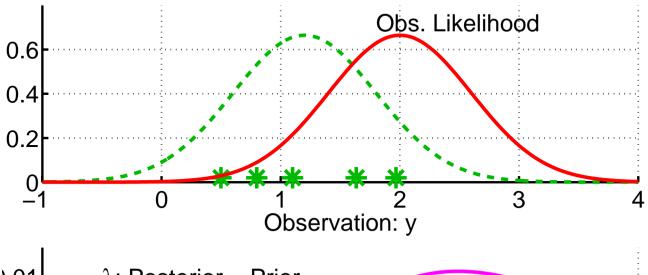

Very little information about  $\lambda$  in a single observation.

Posterior and prior are very similar.

Normalized posterior indistinguishable from prior.

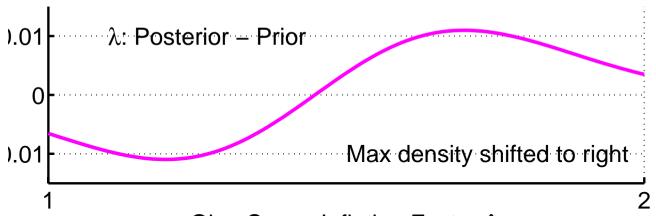

$$p(\lambda, t_k | Y_{t_k}) = p(y_k | \lambda) p(\lambda, t_k | Y_{t_{k-1}}) / normalization.$$

Very little information about  $\lambda$  in a single observation.

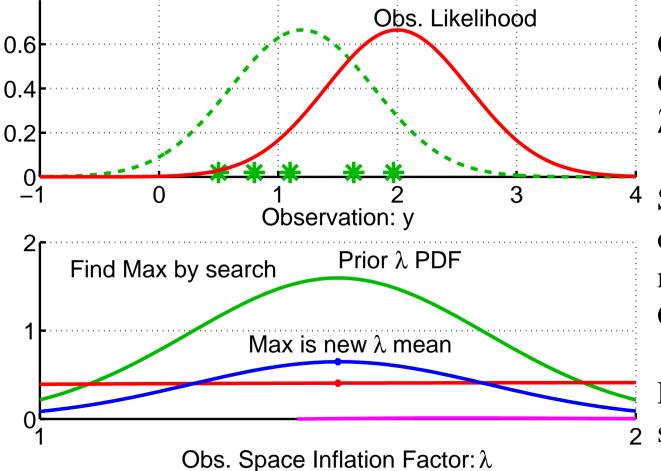

Posterior and prior are very similar.

Difference shows slight shift to larger values of  $\lambda$ .

Obs. Space Inflation Factor:  $\lambda$ 

$$p(\lambda, t_k | Y_{t_k}) = p(y_k | \lambda) p(\lambda, t_k | Y_{t_{k-1}}) / normalization.$$

One option is to use Gaussian prior for λ.

Select max (mode) of posterior as mean of updated Gaussian.

Do a fit for updated standard deviation.

$$p(\lambda, t_k | Y_{t_k}) = p(y_k | \lambda) p(\lambda, t_k | Y_{t_{k-1}}) / normalization.$$

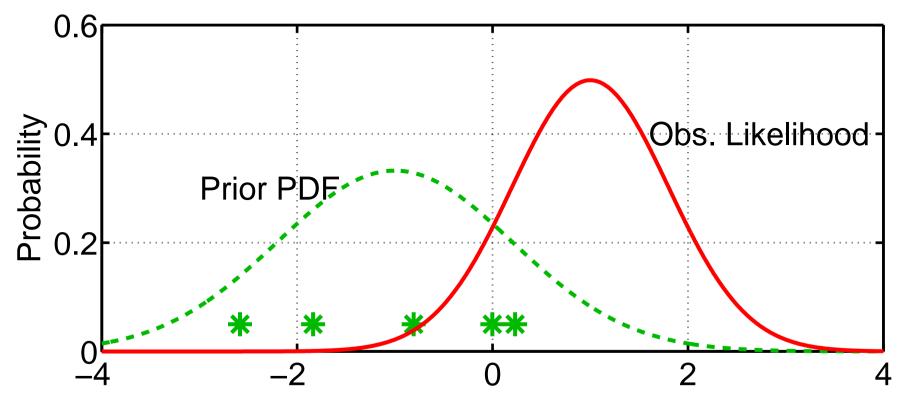

A. Computing updated inflation mean,  $\bar{\lambda}_u$ .

Mode of  $p(y_k|\lambda)p(\lambda, t_k|Y_{t_{k-1}})$  can be found analytically! Solving  $\partial [p(y_k|\lambda)p(\lambda, t_k|Y_{t_{k-1}})]/\partial \lambda = 0$  leads to 6th order poly in  $\theta$  This can be reduced to a cubic equation and solved to give mode. New  $\bar{\lambda}_u$  is set to the mode.

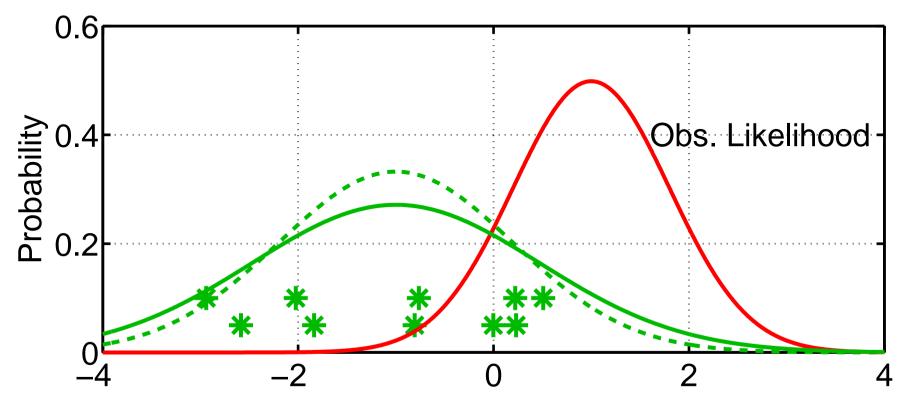

This is relatively cheap compared to computing regressions.

A. Computing updated inflation variance,  $\sigma_{\lambda, u}^2$ 

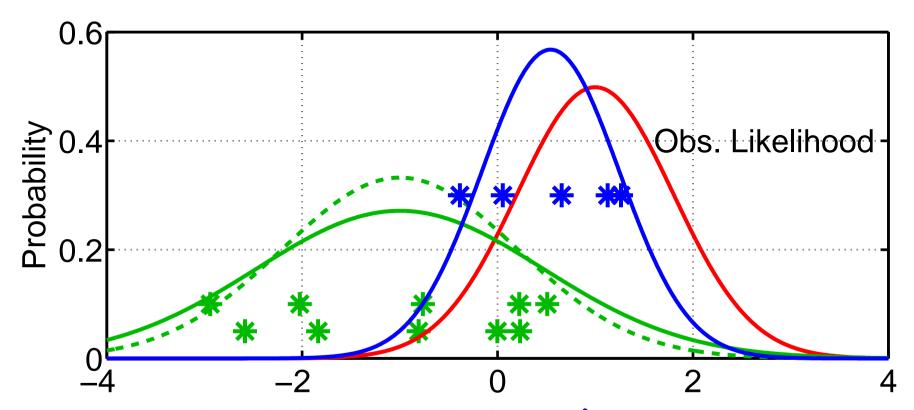

- 1. Evaluate numerator at mean  $\bar{\lambda}_u$  and second point, e.g.  $\bar{\lambda}_u + \sigma_{\lambda, p}$ .
- 2. Find  $\sigma_{\lambda, u}^2$  so  $N(\bar{\lambda}_u, \sigma_{\lambda, u}^2)$  goes through  $p(\bar{\lambda}_u)$  and  $p(\bar{\lambda}_u + \sigma_{\lambda, p})$
- 3. Compute as  $\sigma_{\lambda, u}^2 = -\sigma_{\lambda, p}^2 / 2 \ln r$  where  $r = p(\bar{\lambda}_u + \sigma_{\lambda, p}) / p(\bar{\lambda}_u)$

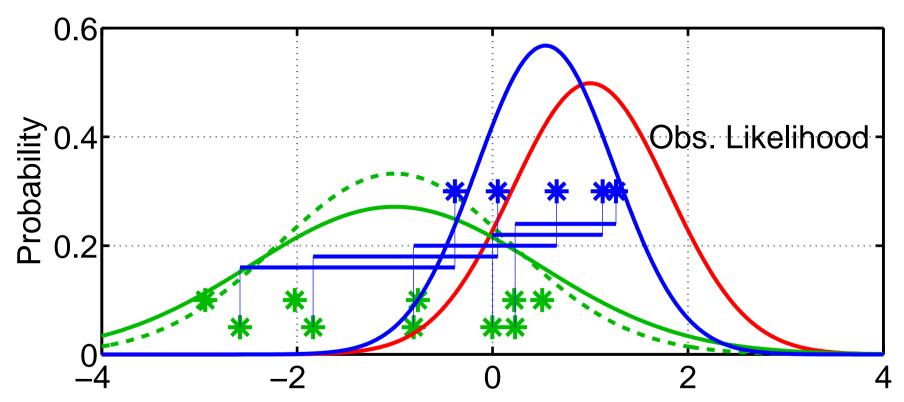

1. Compute updated inflation distribution,  $p(\lambda, t_k | Y_{t_k})$ .

- 1. Compute updated inflation distribution,  $p(\lambda, t_k | Y_{t_k})$ .
- 2. Inflate ensemble using mean of updated  $\lambda$  distribution.

- 1. Compute updated inflation distribution,  $p(\lambda, t_k | Y_{t_k})$ .
- 2. Inflate ensemble using mean of updated  $\lambda$  distribution.
- 3. Compute posterior for y using inflated prior.

- 1. Compute updated inflation distribution,  $p(\lambda, t_k | Y_{t_k})$ .
- 2. Inflate ensemble using mean of updated  $\lambda$  distribution.
- 3. Compute posterior for y using inflated prior.
- 4. Compute increments from ORIGINAL prior ensemble.

## Adaptive Observation Space Inflation in DART

After

Before

```
Assimilation

inf upper bound
                        = 1000000.0
                                                 1000000.0.
inf_sd_lower_bound
                        = 0.0.
                                                 0.0
                                                               Lower bound on s.d.
```

Try this in Lorenz-96 (verify other aspects of input.nml).

Use 40 member ensemble. (set *ens\_size* = 40 in *filter\_nml*).

Set red values as above for adaptive observation space inflation.

## Adaptive Observation Space Inflation in Lorenz-96

Run the filter

Examine performance with *plot\_total\_err* in matlab

Time series of inflation and standard deviation are in *prior\_inflate\_diag* 

Inflation adjusts with time

Standard deviation is non-increasing

## Algorithmic variants:

1. Increase prior y variance by adding random gaussian noise.

As opposed to 'deterministic' linear inflating.

Set *inf\_deterministic* in first column to .false.

Change it back to .true. after checking this out.

2. Just have a fixed value for obs. space  $\lambda$ 

Cheap, handles blow up of state vars unconstrained by obs.

We already tried this in section 9.

# Algorithmic variants:

3. Fix value of  $\lambda$  standard deviation,  $\sigma_{\lambda}$ .

Reduces cost, computation of  $\sigma_{\lambda}$  can sometimes be tricky.

Avoids  $\sigma_{\lambda}$  getting small (error model filter divergence, Yikes!).

Have to have some intuition about the value for  $\sigma_{\lambda}$ .

This appears to be most viable option for large models.

Values of  $\sigma_{\lambda} = 0.05$  to 0.10 work for very broad range of problems.

This is a sampling error closure problem (akin to turbulence).

## To fix $\sigma_{\lambda}$ :

Set *inflate\_sd\_initial* to fixed value, for instance 0.10, Set *inflate\_sd\_lower\_bound* to same value. (s.d. can't get any smaller).

Try this in lorenz-96. Look at how the inflation varies.

## Potential problems with observation space adaptive inflation

- 1. Very heuristic.
- 2. Error model filter divergence (pretty hard to think about).
- 3. Equilibration problems, oscillations in  $\lambda$  with time.
- 4. Not clear that single distribution for all observations is right.

5. Amplifying unwanted model resonances (gravity waves)

Try turning this on in 9var model.

Fixed 0.05 for *cov\_inflate\_sd*, *sd\_lower\_bound*.

Behavior set by value of *cov\_inflate* in *assim\_tools\_nml*.

# Simulating Model Error in 40-Variable Lorenz-96 Model

Inflation can deal with all sorts of errors, including model error.

Can simulate model error in lorenz-96 by changing forcing.

Synthetic observations are from model with forcing = 8.0.

Use *forcing* in *model\_nml* to introduce model error.

Try forcing values of 7, 6, 5, 3 with and without adaptive inflation.

The F = 3 model is periodic, looks very little like F = 8.

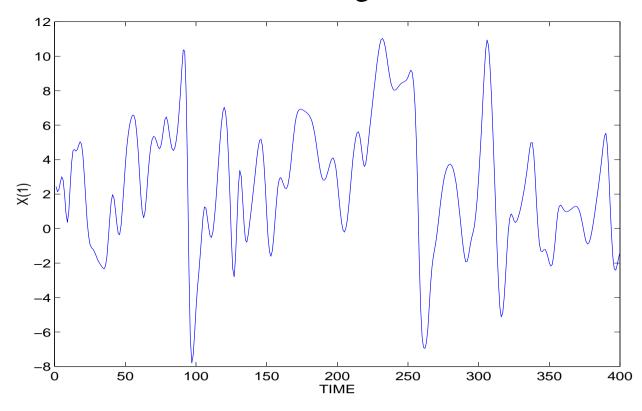

## Simulating Model Error in 40-Variable Lorenz-96 Model

40 state variables:  $X_1, X_2, ..., X_N$ 

$$dX_i / dt = (X_{i+1} - X_{i-2})X_{i-1} - X_i + F;$$

i = 1,..., 40 with cyclic indices

Use F = 8.0, 4th-order Runge-Kutta with dt=0.05

Time series of state variable from free L96 integration

# Experimental design: Lorenz-96 Model Error Simulation

Truth and observations comes from long run with F=8

200 randomly located (fixed in time) 'observing locations'

Independent 1.0 observation error variance

Observations every hour

 $\sigma_{\lambda}$  is 0.05, mean of  $\lambda$  adjusts but variance is fixed

4 groups of 20 members each (80 ensemble members total)

Results from 10 days after 40 day spin-up

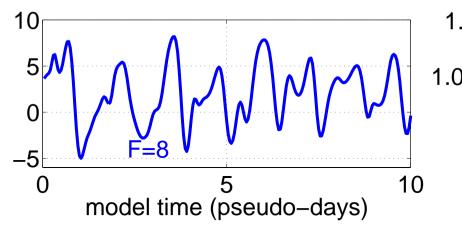

Vary assimilating model forcing: F=8, 6, 3, 0

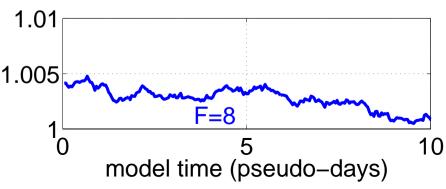

Simulates increasing model error

# Assimilating F=8 Truth with F=8 Ensemble

Prior RMS Error, Spread, and λ Grow as Model Error Grows

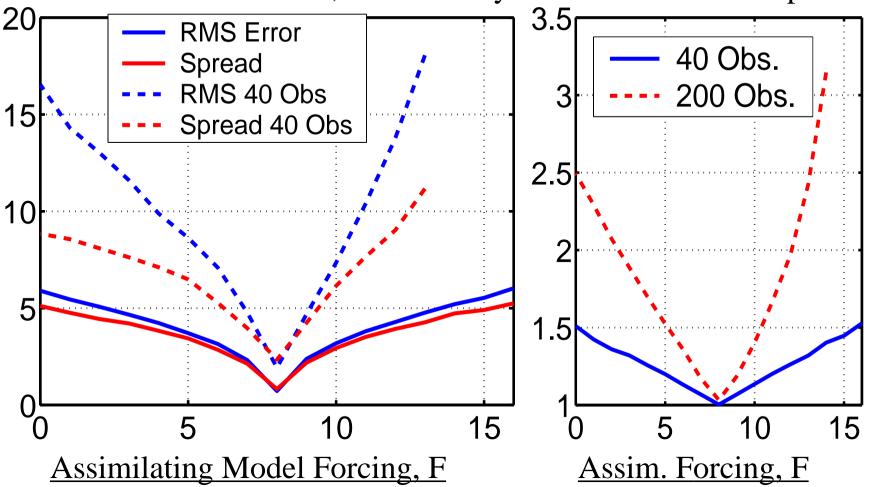

# Base case: 200 randomly located observations per time

(Error saturation is approximately 30.0)

<u>Prior RMS Error, Spread, and λ Grow as Model Error Grows</u>

Less well observed case, 40 randomly located observations per time

# Adaptive State Space Inflation Algorithm

Suppose we want a global state space inflation,  $\lambda_s$ , instead.

Make same least squares assumption that is used in ensemble filter.

Inflation of  $\lambda_s$  for state variables inflates obs. priors by same amount.

Get same likelihood as before:  $p(y_o|\lambda) = (2\Pi\theta^2)^{-1/2} \exp(-D^2/2\theta^2)$ 

$$\theta = \sqrt{\lambda_s \sigma_{prior}^2 + \sigma_{obs}^2}$$

Compute updated distribution for  $\lambda_s$  exactly as for observation space.

# Implementation of Adaptive State Space Inflation Algorithm

- 1. Apply inflation to state variables with mean of  $\lambda_s$  distribution.
- 2. Do following for observations at given time sequentially:
  - a. Compute forward operator to get prior ensemble.
  - b. Compute updated estimate for  $\lambda_s$  mean and variance.
  - c. Compute increments for prior ensemble.
  - d. Regress increments onto state variables.

All the algorithmic variants could still be applied. What are relative characteristics of these algorithms?

## Experimenting with spatially-constant state space inflation

To try adaptive state inflation, set  $inf\_flavor=3$  in first column. May help to increase initial value,  $inf\_initial$ Diagnostics are in  $Prior\_Diag.nc$  file;
This can be viewed with ncview (more on this later)
Final values are in  $prior\_inflate\_restart$  file

# Spatially varying adaptive inflation algorithm:

Have a distribution for  $\lambda$  at for each state variable,  $\lambda_{s,i}$ 

Use prior correlation from ensemble to determine impact of  $\lambda_{s,i}$  on prior variance for given observation.

If  $\gamma$  is correlation between state variable i and observation then

$$\theta = \sqrt{[1 + \gamma(\sqrt{\lambda_{s,i}} - 1)]^2 \sigma_{prior}^2 + \sigma_{obs}^2}$$

Equation for finding mode of posterior is now full 12th order:

Analytic solution appears unlikely.

Can do Taylor expansion of  $\theta$  around  $\lambda_{s,i}$ .

Retaining linear term is normally quite accurate.

There is an analytic solution to find mode of product in this case!

## Experimenting with spatially-constant state space inflation

To try adaptive state inflation, set <code>inf\_flavor=2</code> in first column. May help to increase initial value, <code>inf\_initial</code>
Diagnostics are in <code>Prior\_Diag.nc</code> file;

This can be viewed with <code>ncview</code>
Final values are in <code>prior\_inflate\_restart</code> file

#### **Posterior Inflation**

So far, we've always used the first column of the inflation namelist Inflation is performed after model advances but before assimilation Can also do posterior inflation using second column This does inflation after assimilation but before model advance Technically, this is cheating except in the limit of many observations Assumption that observations and error are independent is lost Helps to increase variance in forecasts

Can also do both prior and posterior inflation (use both columns) Diagnostics are in same files with 'post' instead of 'prior'

## Combined model and observational error variance adaptive algorithm

Is this really possible. Yes, in certain situations... Is there enough information available?

Spatially-vary inflation for state

Inflation factor for different sets of observations (all radiosonde T's)

$$\theta = \sqrt{\left[1 + \gamma(\sqrt{\lambda_{s,i}} - 1)\right]^2 \sigma_{prior}^2 + \lambda_o \sigma_{obs}^2}$$

Different  $\lambda$ 's see different observations

Initial tests in L96 with model error AND incorrect obs. error variance can correct for both!!!
